ABSTRACT

Introduction: In aging there are several physiological and biochemical changes, being recurrent pathologies, such as osteoarthritis (OA). **Objective:** This study aimed to correlate levels of knee osteoarthritis with alteration of balance and quality of life in the elderly. **Methodology:** It is a study observational, cross-sectional descriptive study performed at a Clinical School. The socio-demographic questionnaire, Visual Analogue Scale (EVA), Berg Balance Scale, Tinetti Test, Time Up Go Test (TUGT), Scale Somewhat functional of Lequesne, SF-36 and WHOQOL-Bref. The data were analyzed Statistically, using software R version 3.2.4, with values of significance ($p < 0.05$). **Results:** The sample consisted of 19 elderly individuals, 88.88% female, with a mean age of 66.78 years. In VAS, the mean score was 5.11; already in Tinetti was 19. The mean in the BERG scale was 40.95 and the time during the TUG Test was 22.56s. In Lequesne we obtained as a result 12.53. The lowest score of SF-36 was in the Pain domain (46,17); already in WHOQOL-Bref, was Environment (12,53). **Conclusion:** It is concluded that the found findings give indications that OA knee is a condition that interferes with the quality of life, as well as in the compromising the balance.
